ABSTRACT. In this paper we introduce a class of hyperfields which contains non quotient hyperfields. Thus we give a negative answer to the question of whether every hyperfield is isomorphic to a quotient \( \frac{K}{G} \) of a field \( K \) by some subgroup \( G \) of its multiplicative group.

KEY WORDS AND PHRASES. Hypercomposition, hyperfield, quotient hyperfield, hyperring.

1980 AMS SUBJECT CLASSIFICATION CODE. 12K99.

1. INTRODUCTION

A hyperfield is a triplet \((H, +, \cdot)\) where \( H \) is a non-empty set, \( + \) is a hypercomposition (i.e., a mapping whose domain is \( H \times H \) and whose range is the power set of \( H \)), and \( \cdot \) an internal composition of \( H \) (i.e., for every \( x, y \in H \), \( x \cdot y \in H \)). These two operations satisfy the following axioms:

I. Multiplicative axiom

\( H \) is an almost-group with regard to the multiplication. An almost-group is a semigroup \( S \), which is the union \( G \cup \{0\} \), where \( G \) is a group and 0 a bilaterally absorbing element of \( S \). By \( 1 \) we shall denote its neutral element and by 0 its absorbing element.

II. Additive axioms

(i) \( x + y = y + x \)
(ii) \( (x + y) + z = x + (y + z) \)
(iii) For every \( x \in H \), there exists one and only one \( x' \in H \) such that \( 0 \in x + x' \). \( x' \) is written \( -x \) and called the opposite of \( x \); moreover we shall write \( x - y \) instead of \( x + (-y) \).
(iv) \( z \in x + y \) implies that \( y \in z - x \)

III. Distributive axiom

\( z \cdot (x + y) = z \cdot x + z \cdot y \), \( (x + y) \cdot z = x \cdot z + y \cdot z \)

We remark that:

(a) By usual conventions if \( \cdot \) is an internal composition of a set \( E \) and \( x, y \) are
subsets of \( E \), \( X \cdot Y \) is the set of all \( x \cdot y \) such that \((x,y) \in X \cdot Y \). If "\( \cdot \)" is a hypercomposition in \( E \) then \( X \cdot Y \) signifies the union \( \bigcup_{(x,y) \in X \cdot Y} x \cdot y \). In both cases \( x \cdot Y \) and \( X \cdot y \) will have the same meaning as \( \{x\} \cdot Y \) and \( X \cdot \{y\} \) respectively.

(b) By virtue of axioms II.(iii) and II.(iv) one has
\[ x + 0 = x \text{ for each } x \in H \]
Indeed; \( 0 \cdot x = x \) so \( x \in x \cdot 0 \). Let's suppose that some \( y \) different than \( x \) belongs to \( x \cdot 0 \). Then \( 0 \cdot x = y \) which is absurd because of II.(iii). So \( x + 0 = x \).

Also, because \( + \) is a hypercomposition, the distributive axiom gives:
\[ (a + b)(c + d) = ac + ad + bc + bd. \] (properties of hyperfields can be found in [3], [5] )

(c) If we replace the multiplicative axiom I by
I'. \( H \) is a multiplicative semigroup having a bilaterally absorbing element \( 0 \).
we obtain a more general structure \((H,+,* )\) which is called hyperring. (see [4], [6])

The concept of the hyperfield has been introduced by M. Krasner in his study [1].

The hyperfield that occurs there was obtained by considering a quotient of the type \( K / \sim \)
where \( K \) is a valued field and \( \sim \) an equivalence relation defined from the field's valuation. This hyperfield was called the residual of \( K / \sim \).

2. THE QUOTIENT HYPERFIELD.

Let \( F \) be a field and \( G \) a subgroup of \( F \)'s multiplicative group. Then the multiplicative classes modulo \( G \) in \( F \) form a partition of \( F \). We shall denote by \( F \) the set of the classes of this partition. A multiplication can be introduced in \( F \) by defining the product \( x \cdot y \) of two classes \( x,y \) to be the class which results from their setwise product. It can also be proved (see [2]) that if we add \( x,y \) as subsets of \( F \), the set that results is a union of classes modulo \( G \). This enables us to define the sum \( x + y \) of \( x,y \) to be the set of all classes \( z \in F \) which are contained in the setwise sum of \( x,y \). \( F \) endowed with these two operations becomes a hyperfield ([2]) called quotient hyperfield of \( F \) by \( G \).

If \( F \) is a ring and \( G \) a normal subgroup of \( F^* \) \((= F \setminus \{0\})\) (that is a subset of \( R \), such that \((G,\cdot)\) is a group, and \( xG = Gx \) for all \( x \) in \( R \) ) then \( F \) will be a hyperring called the quotient hyperring of \( F \) by \( G \).

The question that Krasner sets ([2]) is whether there are other hyperfields besides the quotient hyperfields. Indeed it is quite important to find out how rich the class of all hyperfields is, for if there were only quotient hyperfields then a good part of hyperfield theory could have been deduced directly from corresponding results in field theory.

At first one can notice that the residual hyperfields are always quotient hyperfields. Next we shall prove that every subhyperfield of a quotient hyperring is a quotient of a field by a multiplicative group. Indeed let \( \frac{R}{G} \) be a hyperring and \( \frac{F}{G} \) a subhyperfield of \( \frac{R}{G} \). Then

**Lemma 1.** If \( uG \) is the unit of \( \frac{F}{G} \), then \( uG \) is a multiplicative group.
PROOF. Let $x = uy$ be an element of $uG$. Since $uG = Gu$, we have:
$xuG = (uy)uG = u(uy')G = u^2G \subseteq uG \cdot uG = uG$. So the class $xuG$ is a subset of $uG$, thus $xuG = uG$. In the same way we can show that $uGx = uG$ and therefore $uG$ is indeed a group.

Now if we denote by $[[FG]]$ the subring of $R$ which is generated by the set $FG$, we observe that $[[FG]] = uG [[FG]] = [[FG]] uG$.

**Lemma 2.** The unit of $uG$ is also the unit of $[[FG]]$.

**Proof.** Let $e$ be the unit of $uG$. If $s \in [[FG]]$ then there exist $s' \in [[FG]]$ and $\gamma \in G$ such that $s = s'(uy)$. Thus we have: $se = (s'(uy))e = s'((uy)e) = s'(uy) = s$. Similarly $es = s$ and so $e$ is the unit of $[[FG]]$.

**Proposition 1.** Let $R$ be a ring, $G$ a normal multiplicative subgroup of $R$ and $\frac{R}{G}$ the quotient hyperring of $R$ by $G$. Then every subhyperfield of $\frac{R}{G}$ is the quotient of a subfield of $R$ by some subgroup of this subfield's multiplicative group.

**Proof.** Let $\frac{F}{G}$ be a subhyperfield of $\frac{R}{G}$ and let $uG$ be its unit. We observe that $\frac{F}{G} = \frac{[[FG]]}{uG}$. Now since $[[FG]]$ is a hyperfield, for every $t \in [[FG]]$ there exists an element $t' \in [[FG]]$ such that $tG \cdot t'G = uG$, and therefore there exist $\gamma, \gamma' \in G$ such that $(t\gamma) \cdot (t'\gamma') = e$, where $e$ is both the unit of $G$ and the unit of $[[FG]]$. Thus $t'\gamma'$ is the inverse element of $t$ and therefore $[[FG]]$ is a field.

3. **Non Quotient Hyperfields.**

We shall construct a class of hyperfields which contains hyperfields that are not isomorphic to quotient ones. For this purpose we consider a commutative multiplicative almost-group $(H, \cdot)$ in which we introduce a hypercomposition $+$ defined as follows:

$$x + y = \{x, y\} \quad \text{if } x, y \neq 0 \text{ and } x \neq y$$

$$x + x = H \setminus \{x\} \quad \text{if } x \neq 0$$

and

$$x + 0 = 0 + x = x \quad \text{for every } x \in H$$

Then:

**Proposition 2.** The triplet $(H, +, \cdot)$ is a hyperfield.

**Proof.** At first one can notice that the opposite of $x$ is $x$ itself since $0 \in x + x$. Next it is obvious that the hypercomposition is commutative and that the associativity is valid when one of $x, y, z$ is equal to $0$. Now if $x, y, z \neq 0$ and distinct, then we have:

$$x + (y + z) = x + \{y, z\} = (x + y)U(x + z) = \{x, y\}U\{x, z\} = \{x, y, z\}$$

A similar calculation shows $(x + y) + z = \{x, y, z\}$. Finally if two of $x, y, z$ are equal to each other; for example $x = y$, we have:

$$x + (y + z) = x + (x + z) = x + \{x, z\} = (x + x)U(x + z) = \{H \setminus \{x\}\}U\{x, z\} = H$$

and

$$(x + y) + z = (x + x) + z = [H \setminus \{x\}] + z \supseteq (z + z)U(w + z) = \{H \setminus \{z\}\}U\{w, z\} = H,$$ with $w \neq z$

Now as far as the axiom II.iv. is concerned we have:

1. if $y = x$ then $x + y = x + x = H \setminus \{x\}$. This means that for every $z \in H \setminus \{x\}$ we must have $x \in z + x$ which is in fact true.
(ii) If \( y \neq x \), 0 then \( x + y = \{x, y\} \), thus \( z = x \) or \( z = y \). If \( z = x \) then \( x \in z + y = \{z, y\} \) and if \( z = y \) then \( x \in z + y = H \setminus \{y\} \). So this axiom is valid as well.

Finally it is straightforward to verify the distributive axiom.

**Theorem.** The class of the hyperfields constructed as above contains elements that do not belong to the class of quotient hyperfields.

**Proof.** We choose an almost group \((H, \cdot)\) with \( \text{card } H > 3 \) and such that \( x^2 = 1 \) for every \( x \in H \setminus \{0\} \). Next we consider the hyperfield \((H, +, \cdot)\) which is constructed according to the above method and we suppose that this hyperfield is isomorphic to a quotient hyperfield \( F_G \) then for \( \frac{F}{G} \) the following must be valid:

(i) \( xG \cdot \overline{G} = G \) or \( x^2G = G \) for every \( x \in F \)

(ii) \( G = \overline{G} \)

(iii) \( G \nleftarrow G = (\overline{G} \setminus G \) from which \( G + G = F \setminus G \)

Because of (i) \( G \) must contain all the squares of \( F \). But if \( F \) is not of characteristic 2 then every element of \( F \) can be written as a difference of two squares:

\[
\begin{align*}
\sqrt{x} &= \left(\frac{x + 1}{2}\right)^2 - \left(\frac{x - 1}{2}\right)^2 = \frac{(x + 1)^2}{2} + (-1)\left(\frac{x - 1}{2}\right)^2
\end{align*}
\]

So we have \( G = G = G + G = F \). This contradicts (iii).

Now if the characteristic of \( F \) is 2 then the sum of two squares is always a square; thus \( G \subseteq G + G \), which contradicts again (iii). So \( H \) cannot be isomorphic to any quotient hyperfield.

**Remarks.** (a) This theorem gives something more, that is, \( H \) cannot be isomorphic even to a subhyperfield of a quotient hyperring.

(b) Two other classes of hyperfields completely different can be found in [7]. The problem of those hyperfields' isomorphism to quotient hyperfields is also discussed there but no final answer is given.

Call for Papers

As a multidisciplinary field, financial engineering is becoming increasingly important in today’s economic and financial world, especially in areas such as portfolio management, asset valuation and prediction, fraud detection, and credit risk management. For example, in a credit risk context, the recently approved Basel II guidelines advise financial institutions to build comprehensible credit risk models in order to optimize their capital allocation policy. Computational methods are being intensively studied and applied to improve the quality of the financial decisions that need to be made. Until now, computational methods and models are central to the analysis of economic and financial decisions.

However, more and more researchers have found that the financial environment is not ruled by mathematical distributions or statistical models. In such situations, some attempts have also been made to develop financial engineering models using intelligent computing approaches. For example, an artificial neural network (ANN) is a nonparametric estimation technique which does not make any distributional assumptions regarding the underlying asset. Instead, ANN approach develops a model using sets of unknown parameters and lets the optimization routine seek the best fitting parameters to obtain the desired results. The main aim of this special issue is not to merely illustrate the superior performance of a new intelligent computational method, but also to demonstrate how it can be used effectively in a financial engineering environment to improve and facilitate financial decision making. In this sense, the submissions should especially address how the results of estimated computational models (e.g., ANN, support vector machines, evolutionary algorithm, and fuzzy models) can be used to develop intelligent, easy-to-use, and/or comprehensible computational systems (e.g., decision support systems, agent-based system, and web-based systems).

This special issue will include (but not be limited to) the following topics:

- **Application fields:** asset valuation and prediction, asset allocation and portfolio selection, bankruptcy prediction, fraud detection, credit risk management
- **Implementation aspects:** decision support systems, expert systems, information systems, intelligent agents, web service, monitoring, deployment, implementation

Authors should follow the Journal of Applied Mathematics and Decision Sciences manuscript format described at the journal site http://www.hindawi.com/journals/jamds/. Prospective authors should submit an electronic copy of their complete manuscript through the journal Manuscript Tracking System at http://mts.hindawi.com/, according to the following timetable:
